Amendment and Response Under 37 C.F.R. 1.116
Applicant: Sanjay Bhardwaj
Serial No.: 09/771,172
Filed: January 26, 2001
Docket No.: I331.146.101/02P00670US
Title: METHOD AND APPARATUS FOR BYTE ROTATION

IN THE CLAIMS

Please cancel claims 23, 24, 26-28, 36-38, 40-42, 44, and 45.

Please amend claims 25, 30-32, 34, 35, 43, and 47-49 as follows:

1-22.   (Cancelled)

23.   (Cancelled)

24.   (Cancelled)

25.   (Currently Amended) The apparatus of claim ~~23~~29, wherein said combiner includes a selector having inputs respectively coupled to said input and said buffer, and having an output coupled to said data path.

26-28. (Cancelled)

29.   (Previously Presented) A data alignment apparatus, comprising:

an input for receiving an input temporal series of parallel-formatted input groups of digital data units;

a data aligner coupled to said input and responsive to said input series for producing an output temporal series of parallel-formatted output groups of said digital data units;

an output coupled to said data aligner for outputting said output series;

said data aligner including a buffer coupled to said input for storing data units of a first said input group while a second said input group is received at said input, and a combiner coupled to said buffer and said input for producing one of said output groups by combining in parallel format all of said data units stored in said buffer and selected data units of said second input group;

Amendment and Response Under 37 C.F.R. 1.116
Applicant: Sanjay Bhardwaj
Serial No.: 09/771,172
Filed: January 26, 2001
Docket No.: I331.146.101/02P00670US
Title: METHOD AND APPARATUS FOR BYTE ROTATION

a data path coupled to said combiner and said output for permitting said one output group to be transferred to said output without being stored in said buffer;

wherein said combiner comprises a rotator coupled to said input for rotating the data units of said second input group to position said selected data units of said second input group for said combiner to parallel concatenate said selected data units with all of said data units stored in said buffer to produce said one output group;

wherein said data aligner includes a controller for determining a rotation amount by which said rotator is to rotate the data units of said second input group, said controller having an output coupled to said rotator for providing to said rotator information indicative of said rotation amount;

wherein said controller determines said rotation amount based on a data unit storage capacity of said buffer; and

a further buffer coupled to said input and said combiner for storing said second input group while said data units of said first input group are stored in said first-mentioned buffer, wherein said controller determines said rotation amount based on a sum of respective data unit storage capacities of said buffers.

30.   (Currently Amended) The apparatus of Claim 2329, wherein each said input group is one of a head element, a body element and a tail element of a data packet.

31.   (Currently Amended) The apparatus of Claim 2329, wherein each of said data units is a byte.

32.   (Currently Amended) The apparatus of Claim 2329, wherein said buffer has a maximum data unit storage capacity that is equal to a maximum data unit capacity of the input groups in said input series.

33.   (Previously Presented) The apparatus of Claim 32, wherein said maximum data unit storage capacity of said buffer is 16 data units.

Amendment and Response Under 37 C.F.R. 1.116
Applicant: Sanjay Bhardwaj
Serial No.: 09/771,172
Filed: January 26, 2001
Docket No.: I331.146.101/02P00670US
Title: METHOD AND APPARATUS FOR BYTE ROTATION

34.   (Currently Amended) The apparatus of Claim ~~23~~29, wherein said data path bypasses said buffer.

35.   (Currently Amended) A data alignment method, comprising:

receiving an input temporal series of parallel-formatted input groups of digital data units;

in response to the input series, producing an output temporal series of parallel-formatted output groups of said digital data units, including storing data units of a first said input group in a buffer while a second said input group is received;

said producing step including combining in parallel format all of said data units stored in the buffer and selected data units of said second input group to produce one of said output groups~~;, and~~wherein said combining includes rotating the data units of said second input group to position said selected data units of said second input group for parallel concatenation with all of said data units stored in the buffer, and parallel concatenating said selected data units with all of said data units stored in the buffer to produce said one output group;

outputting said one output group for further processing without storing said one output group in the buffer~~.~~;

storing said second input group in another buffer while said data units of said first input group are stored in said first-mentioned buffer; and

determining a rotation amount by which said data units of said second input group are rotated based on a sum of respective data unit storage capacities of said buffers.

36-38. (Cancelled)

39.   (Previously Presented) The method of Claim 35, wherein said outputting step includes said one output group bypassing the buffer.

40-42. (Cancelled)

Amendment and Response Under 37 C.F.R. 1.116
Applicant: Sanjay Bhardwaj

Filed: January 26, 2001
Docket No.: I331.146.101/02P00670US
Title: METHOD AND APPARATUS FOR BYTE ROTATION

43.　　(Currently Amended)　The apparatus of Claim 42~~46~~, wherein said combiner includes a selector having inputs respectively coupled to said rotator and said buffer, and having an output coupled to said data path.

44-45.　(Cancelled)

46.　　(Previously Presented)　An apparatus for interfacing a digital data processor to a digital communication network, comprising:

　　　　a first data port that permits exchange of digital data with the data processor;

　　　　a second data port that permits exchange of digital data with the communication network; and

　　　　a data alignment apparatus coupled between said first and second data ports, including an input for receiving an input temporal series of parallel-formatted input groups of digital data units, a data aligner coupled to said input and responsive to said input series for producing an output temporal series of parallel-formatted output groups of said digital data units, and an output coupled to said data aligner for outputting said output series;

　　　　said data aligner including a buffer coupled to said input for storing data units of a first said input group while a second said input group is received at said input, and a combiner coupled to said buffer and said input for producing one of said output groups by combining in parallel format all of said data units stored in said buffer and selected data units of said second input group; and

　　　　said data alignment apparatus including a data path coupled to said combiner and said output for permitting said one output group to be transferred to said output without being stored in said buffer;

　　　　wherein said combiner comprises a rotator coupled to said input for rotating the data units of said second input group to position said selected data units of said second input group for said combiner to parallel concatenate said selected data units with all of said data units stored in said buffer to produce said one output group;
